

Multi-Writer CDC Challenges

Sunny Bains
PingCAP

FOSDEM 2026

Traditional Replication

Examples

MySQL
binlog

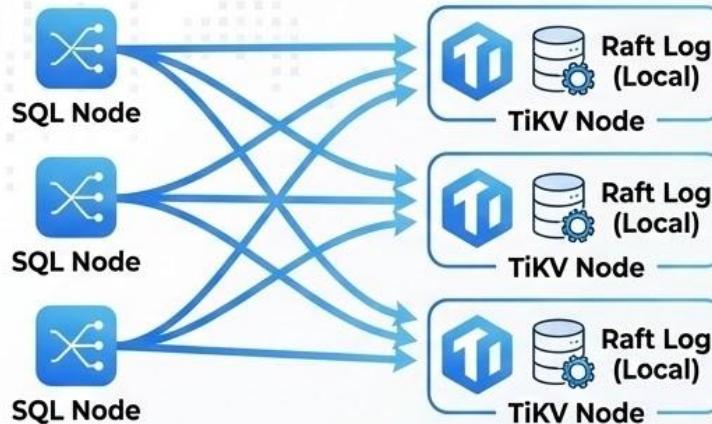

PostgreSQL
WAL replication

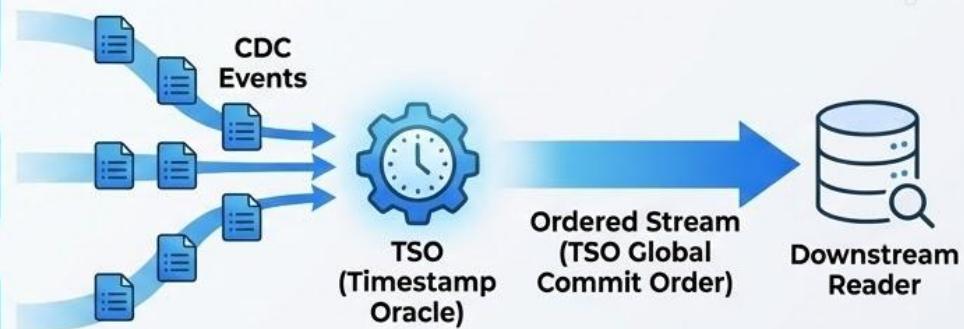

- Single writer
- multiple reader
- Ordering of events
- is implicit

TiDB CDC

Distributed Write Architecture

Global TSO Ordering & Commit

- ▶ Multiple SQL Nodes write to multiple TiKV nodes.
- ▶ Distributed transactions can touch multiple TiKV nodes.
- ▶ The Raft log stores the replicated state machine and distributed transactions.
- ▶ The Raft log is per TiKV node not a global log.

- ▶ CDC Events have to be read from the Raft logs and then ordered according to the global commit order based on the commit TSO when propagating the CDC.
- ▶ Downstream readers must see events in the TSO global order in which they were committed when reading from the CDC stream.

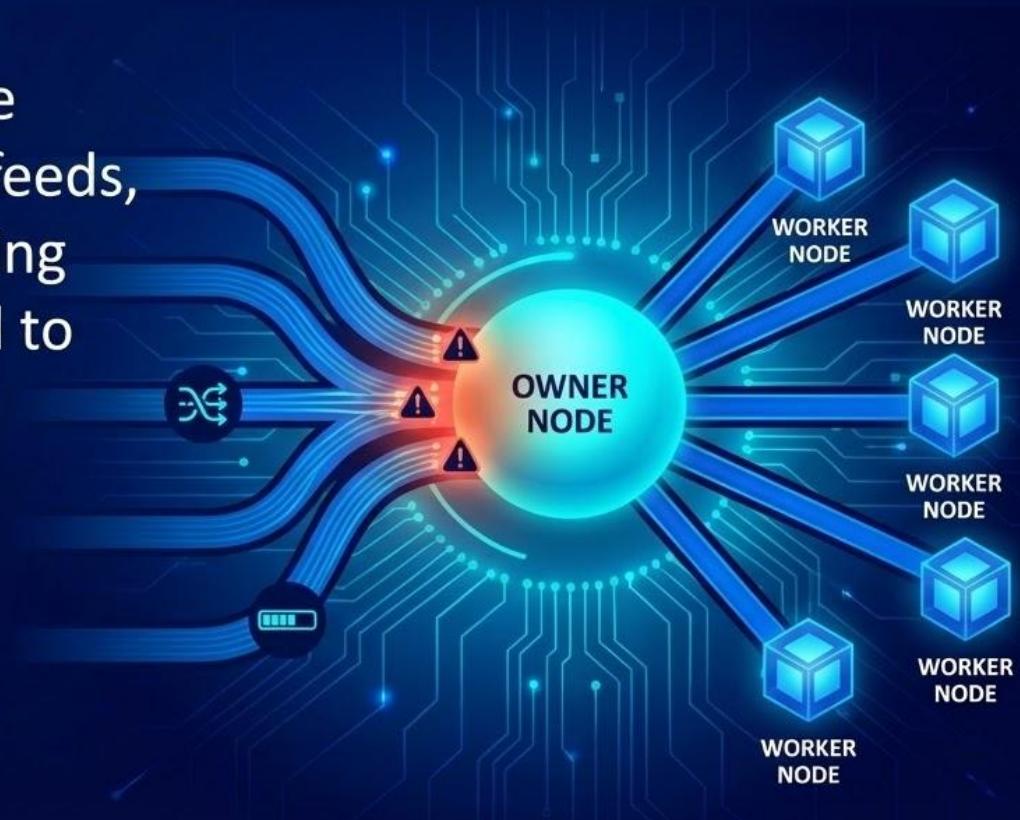

The Ordering Guarantee

The execution order is: DML → DDL → DML. TiCDC ensures schema correctness by coordinating execution.

PREVIOUS ARCHITECTURE

- Centralized Owner node
- Owner handles changefeeds, table progress, scheduling
- Workers tightly coupled to Owner logic

MOTIVATION & BACKGROUND

↗ ↘ Growing cluster scale exposes architectural limits

➡ Owner-centric design becomes a bottleneck

⟳ Increasing complexity impacts stability and operability

🔒 Cloud-native and multi-tenant support are constrained

Scaling Challenges with High Region Count

**1 Million Regions across
3 TiKV Nodes**
• ~333K regions per TiKV

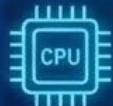

Concurrent gRPC Streams
• ~333K per TiCDC capture

ResolvedTs Messages
• ~333K every tick interval

Memory Pressure
Each Delegate/Resolver holds state

CPU Overhead
Processing millions of small messages

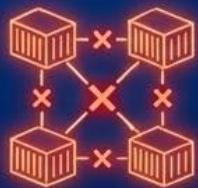

Network Amplification
ResolvedTs fanout

This Creates:

Real-World Symptoms (From TiKV issues):

- ⚠️ CDC endpoint CPU 100% with just 800 ops/s (#9981)
- ⚠️ TiKV OOM from buffered CDC events (#8168, #9996)
- ⚠️ Resolver memory unbounded growth (#15412)

CLOUD-NATIVE CHALLENGES

- Difficult multi-tenancy

- No fine-grained resource control

- High operational complexity

SCALABILITY LIMITATIONS

Owner is a single-point bottleneck

~100k tables, ~400 changefeeds, ~10 nodes

~700MB/s throughput,
~3 DDLs/sec

Old architecture vs new Architecture

The “Classic” TiCDC architecture faced scaling challenges that were addressed in v8.5.4-r1.

⚠ Previous limitations

- **The 50ms Timer Trap:**
“Owner” node’s 50ms polling loop capped DDL speed (~3/sec), introducing a “lag floor.”
- **Stateful/Stateless Mixing:**
Tightly coupled components. Node failure caused massive “Stop-the-world” latency spikes.
- **Large Transaction Buffering:**
GB-sized transactions overwhelmed Sorter memory, leading to OOM errors or disk thrashing.

⬆️ Ongoing & Future Improvements

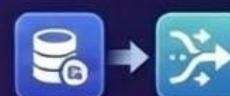

- **Event-Driven Architecture:**
Moving to a purely event-driven model for sub-millisecond processing and higher DDL throughput.

- **Task Splitting:**
Splitting single table replication across multiple nodes for “hotspot” (ultra-high write volume) handling.

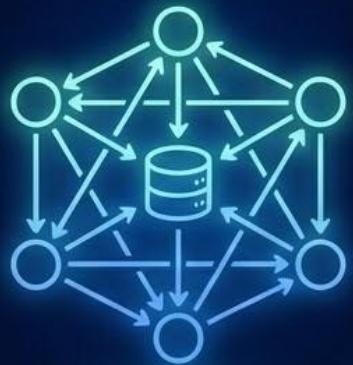

- **Decoupled Log Service:**
Dedicated stateful “Log Service” for sorting/storage, leaving stateless “Processors” to push data, enabling faster scale-out.

Faster Scale-Out

CORE DESIGN PRINCIPLES

Decentralization

Event-driven
processing

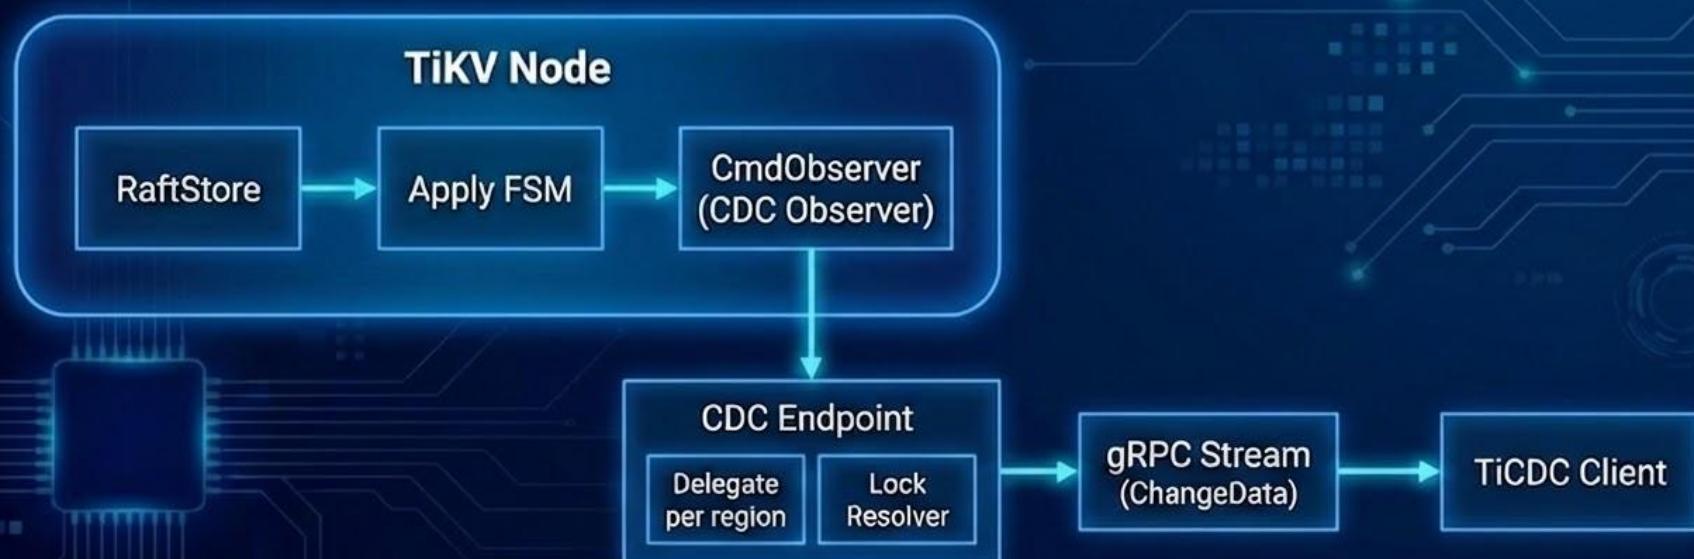

Clear separation
of concerns

NEW ARCHITECTURE COMPONENTS

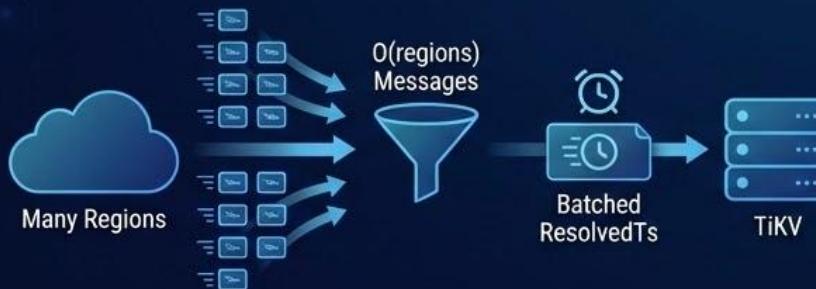

How CDC Hooks into RaftStore (Coprocessor Observer Pattern)

CDC doesn't intercept Raft messages.
Instead, it uses the **Coprocessor Observer** pattern.

Batched ResolvedTs & Multiplexed Streams (Optimizations)

1. Batched ResolvedTs (Network Optimization)

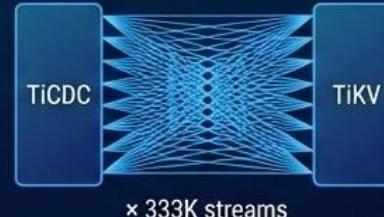

Reduces message count from $O(\text{regions})$ to $O(1)$ per interval.

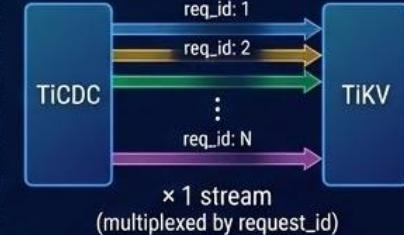

2. Multiplexed Streams (Connection Optimization)

Single gRPC stream handles multiple regions

Before: 1 stream per region

After: 1 stream per store (multiplexed)

The "request_id" field in ChangeDataRequest enables this multiplexing.

Additional Optimizations

3. Region Merge (B-Tree)

4. Memory Quota & Backpressure

When quota exhausted
→ backpressure → slow down event generation.

5. Resolved-by-Raft

Avoids tracking every lock; uses Raft's applied index.

TiCDC New Architecture (v8.5+)

The new architecture fundamentally redesigns for scale:

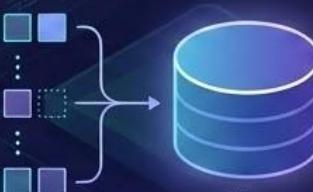

Data sharing

Changefeeds
Changefeeds
Changefeeds
Changefeeds
Changefeeds

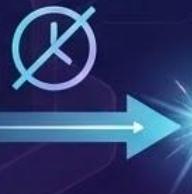

Multiple changefeeds
share one Log Service

Disk-backed

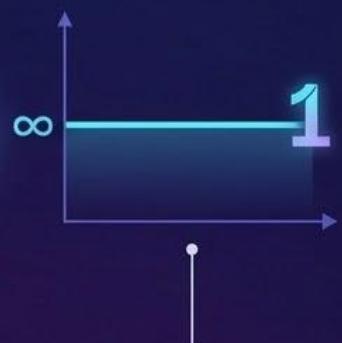

Events stored on
disk, not memory

Event-driven

No timer polling
overhead

$O(1)$ complexity

Unaffected by
table count

Mounter's Role

Sits between the sorter and sink in the data flow:

What It Does

Decodes raw KV pairs

Deserializes TiKV CDC low-level key-value changes into structured row data.

Schema resolution

Maps raw bytes to column names/types using table schema. Handles mid-stream DDL changes.

Constructs row change events

Produces a canonical representation with table, operation, new, and old column values.

Formats for downstream consumption

Prepares data in formats the sink understands (e.g., SQL, JSON/Avro).

Why It's Separate

- Decoupling encoding logic allows Sorter to work on opaque bytes (faster, simpler) and Sink to receive clean, structured events.
- chip icon The mounter is a **compute-heavy** component (lots of deserialization).

Technical Deep Dive: The Heart of TiCDC

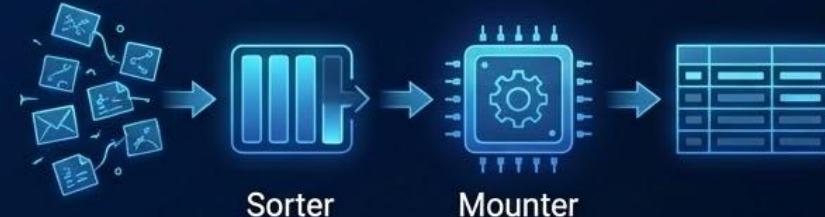

A. The Resolved TS (Timestamp) Mechanism

- **Watermark Tracking:** Each TiKV node maintains a "Resolved TS" (no earlier writes guaranteed).
- **Global Aggregation:** TiCDC pulls Resolved TS from all Regions.
- **The Bar:** Calculates Minimum Resolved TS as the "safe-to-emit" line.

B. Event Sorting and Transaction Reconstruction

- **Sorter:** Buffers and flushes interleaved logs in strict chronological order (often via Pebble).
- **Mounter:** Transforms raw "Key:Value" bytes into RowChangedEvent using schema snapshot.

Cluster Startup Workflow

Instance Join / Leave

Dynamic
registration

Coordinator
rebalances workloads

Automatic
recovery

Special Scenarios

Network isolation
handling

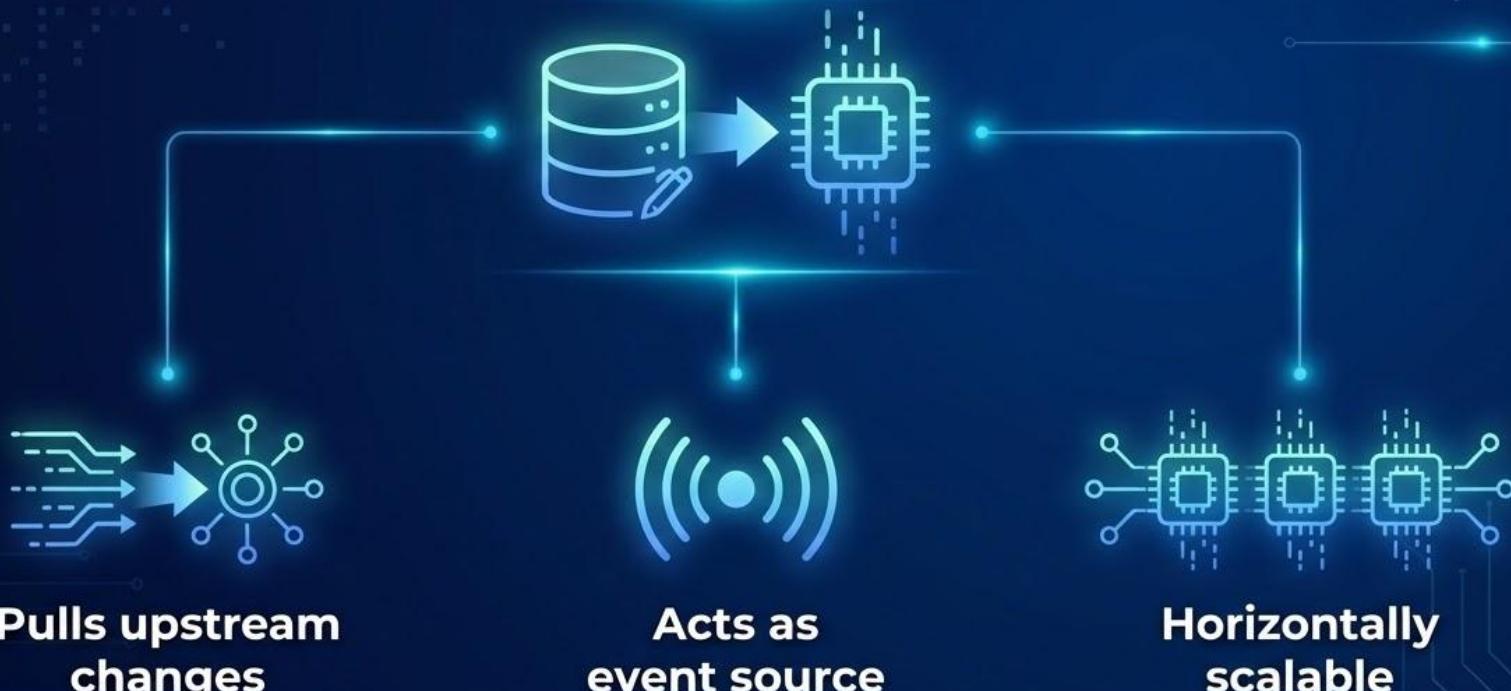

Partitioned tables

Upgrade / downgrade
compatibility

UPSTREAM ADAPTER

LOG SERVICE

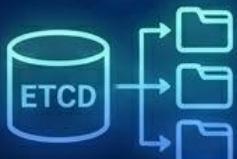

DOWNSTREAM ADAPTER

COORDINATOR

Schedules
changefeeds

Manages
metadata in ETCD

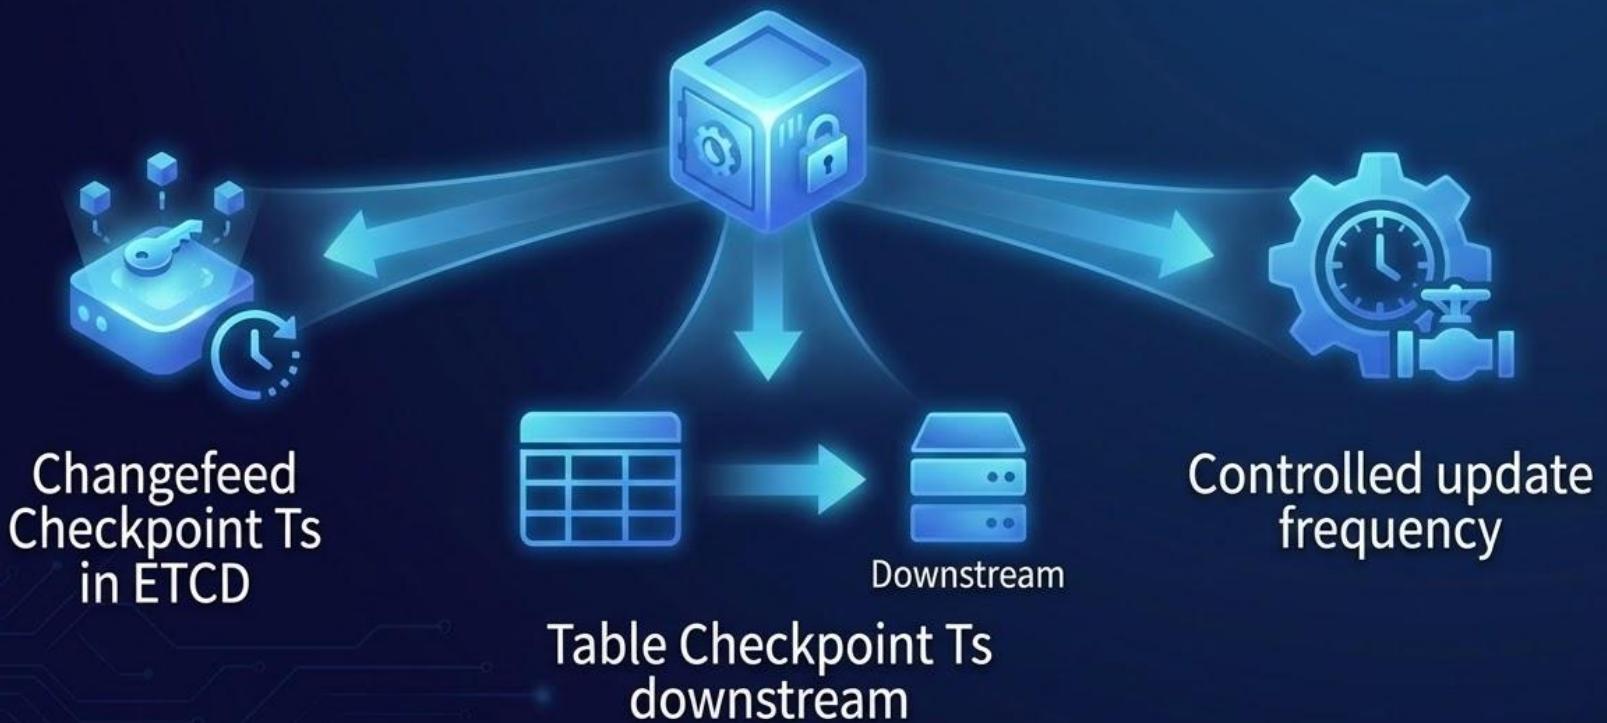

No data-plane
responsibilities

New Changefeed Creation

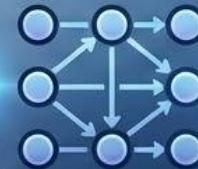

Persistence & Metadata

New Changefeed Creation

- Create maintainer
- Create dispatchers
- Fetch and push events

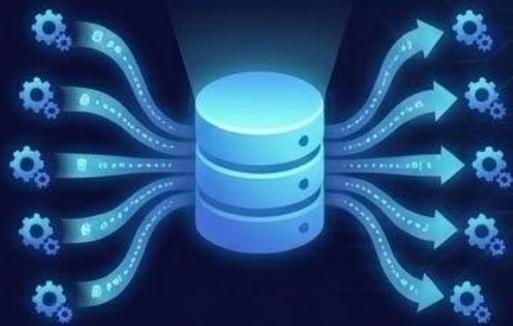

Large Changefeeds & Tables

More changefeeds
supported

Large tables
can be split

Transaction integrity
preserved

Third-Party Sink Support

Golang plugins

RPC/Webhook sinks

Extensible
architecture

Coordinator vs Maintainer

Failure Handling

Crash recovery
via metadata

Automatic state restoration

ETCD-based
leadership

Distributed consensus

Brain-split
prevention

Quorum-based stability

Summary

<https://github.com/pingcap/ticdc>

Linear scalability

Higher throughput

Cleaner architecture

Cloud-native ready
